ACCESSING MODERN CONTRACEPTIVE TECHNOLOGIES IN INDIA

(Received on March 15, 2006)

Abstract : The 'unmet' need for reproductive health care in India requires a wide demand net. Besides 'supply' of oral contraceptives, condoms and IUDs, the 'non-supply' approach for increasing contraceptive prevalence is recommended through education about the variety of safe contraceptives and awareness in the use of traditional methods. Expansion of education is partly responsible for the recent decline in fertility in India, however, gender inequality still prevails with poor sex ratio in urban regions, and deficit of around 35 million girls and women from higher mortality compared to males till the age of 30. The community can become a key force in knowledge sharing for greater contraceptive prevalence and also to support its service sector. Practice of women's reproductive health involves complex socio-cultural-biological interaction in accessing modern contraceptive technologies. A number of interactive factors have been suggested to operate at different hierarchical levels to provide homeodynamic stability to the central event of reproductive health care under a central controller action, the government. While guidelines of the World Health Organization for quality care in family planning should be implemented in rural and urban sectors, efforts should also be made to translate recent advances in contraceptive technology from laboratory to service sector for improving women's reproductive health.

Key words : contraception reproduction unmet need women' health

The third decennial International Conference on Population and Development (ICPD) held in 1994 is a landmark in the history of global population management. It resulted in a paradigm shift in conceptualizing population policy from a top-down bureaucratic, target-driven programme as practiced in many countries including India, to a bottom-up approach that takes into cognizance issues like gender equality and women empowerment as key factors in implementing

the new population policy. It has also resulted in addressing core issues related to education, societal sanctities, economic and political will, women's perspective and awareness about her reproductive and sexual rights and freedom. It also appears imperative that an operative vision for enhancing access to contraceptive technologies, especially the improved, modern ones needs to be evolved in developing countries like India. A few slices of facts shown in Box justify it.

Box 1

Φ1 76 million unintended pregnancies are reported every year in the developing world due to lack of family planning services^a.

Φ2 One in ten pregnancies end in an unsafe abortion, with Asia, Africa and Latin America accounting for the highest numbers. Each year, 19 million abortions are carried out under unsanitary or medically unfit conditions resulting in some 68,000 deaths^b.

Φ3 Poverty and gender discrimination results in poor reproductive health. Anaemia which can lead to post-partum hemorrhage affects 50–70 % of pregnant women in developing countries^c.

Φ4 Maternal death is practically nonexistent in developed nations. Primarily due to poverty and gender inequity in reproductive health matters there is death of one woman every minute in developing countries due to pregnancy related causes^d.

Φ5 Two thirds of maternal deaths in 2000 occurred in 13 of the world's poorest countries, and one quarter of these were in India alone^e.

Φ6 Based on the 1991 Census Data of India, a declining sex ratio from 934 to 929 females to 1000 males observed between 1981 and

1991 resulted from female fetocide, early childhood mortality and malnutrition^f.

There is 'unmet' need in the reproductive health care. The 'unmet' need refers to the need of women and couples who wish to control their fertility but use no method. It includes (i) non-pregnant, non-amenorrheic women who wish to limit their family size, or wish to space births but are not using any contraceptives, (ii) women who are pregnant or amenorrheic, and (iii) women

who report their pregnancy as unwanted or mistimed pregnancy (1). The United Nations' 1999 review of implementation progress adopted benchmark indicators: *reduction of unmet need to half of 1990 levels by 2005* and *satisfaction of all stated fertility desires by 2015* (2). The UNFPA estimated that in 2004 some 137 million women had an 'unmet' need for contraception, another 64 million

were using traditional family planning methods that are less reliable than modern methods, and overall in developing countries, 29 per cent of women had an 'unmet' need for modern contraception (3). Clearly, there are manifold barriers to contraceptive use as shown in Box 2. We need to develop strategies aimed to discourage such practices, promote greater awareness in

reproductive health care along with better client-provider interaction to minimize the 'unmet' need.

In developing countries, many couples have little or no information of contraceptive practices but wish to control their fertility. Such underserved couples have only a limited number of choices available to them or they do not practice contraception. A large number of studies have proposed that education is a strong determinant of fertility; a strong impact of education on fertility decline has been reported and is considered partly responsible for India's recent fertility decline (4). The 1991 census data of India revealed a declining sex ratio from 934 in 1981 to 929 females to 1000 males in 1991, early childhood mortality, malnutrition, female fetocide may all be contributing factors (5). The West Bengal Health report for 2001 reveals an alarming decline in this ratio in the urban setting. Comparison of vital statistics, literacy rate, family welfare services in rural and urban settings of West Bengal in 2001 (see Box 3) reveals an alarming sex ratio of 893 in urban compared to 950 in rural settings albeit with a significantly higher literacy rate and a decreased total fertility rate in the urban population. Incomplete and poor degree of value-added education may be responsible for the gender inequity and decline in sex ratio found in West Bengal.

Women's autonomy that covers economic autonomy, physical autonomy, decision-making autonomy, emotional autonomy and knowledge autonomy are considered to be mediating factors in the causal pathways linking education and fertility. Beside a

Box 2

Major barriers to contraceptive use

Lack of accessible services for modern contraceptive techniques that include oral contraceptives, implants, injections and barrier methods (male and female condoms and diaphragms), and traditional methods including periodic abstinence, withdrawal and lactational amenorrhea (extended breastfeeding) and male and female sterilizations.

Lack of method choices appropriate to the situation of the woman and her family that address cultural sensitivities of bleeding or spotting side effects where blood taboos are prevalent.

Lack of knowledge about the use, safety, effectiveness and availability of contraceptive choices to the woman.

Lack of efficacious client-provider interaction.

Lack of support from the spouse and/or community.

Lack of financial support.

woman's own education that is considered in most studies on fertility, data based on Demographic Health Survey (DHS) reveals that husband's education was very important for good reproductive health (6). The role of social learning and the education of other women residing in the community and its impact on a woman's birth rate has also been well documented, substantiating the earlier proposal of 'mass education' as a key force behind fertility decline (7). The probability of adapting contraception is thus influenced not only by a woman's own education but also by that of others in her community. Community education operating through the use of maternity services and other preventive health services has been shown to have a clear impact on child mortality in India (8).

It is increasingly evident that a women's intent to practice contraception in addition to, assessing the unmet need is important. The intent to practice birth spacing and fertility regulation is likely to rest upon dynamic rather than static component, and is indeed dependent upon multiple factors. It may be associated with social pressures both within and outside her family, by the sudden death of a child, by economic pressures, lack of good family planning services, and non-availability of contraceptive agents.

Based on a survey conducted in rural Madhya Pradesh, a discrepancy was observed between *intent* and *practice* of contraception in a sub-sample of women who had participated in the National Family Health Survey-I (NHFS-I) in 1992–93 and again in 1999 (9). 51% women who were not practicing contraception but planned to do so had acted against their intention by 1999, as did 29% women who intended not to use contraception. Women who intended to use a method and not to have children were more likely to use a method by 1999. The age and death of child were reported to be strong factors associated with inconsistency between a woman's intention and behaviour. In order to reduce the 'unmet' needs a fair assessment of contraceptive intentions is likely to help in the development of family planning programmes by giving due attention to the needs of women who initially intended not to use contraception but do so after a gap of 6–7 years mainly due to attainment of family size (9).

Based on data from the NHFS-I and the NHFS-II it is apparent that the Reproductive

and Child Health Programmes conducted in India in 1992–1993 and again in 1998–1999 were guided by the ‘unmet’ need. While the ‘unmet’ need requires attention, the aim should be focused towards fulfilling the reproductive intentions of couples. Ravindran and Mishra observed that 69 women out of 70 women in rural Tamil Nadu had failed to achieve their reproductive intentions based on the HARI index (Helping Individuals Achieve their Reproductive Intentions) (10). Lack of education, and community support, improper counseling by health workers are the likely causative factors for women to resort to abortion of unwanted pregnancies, and use of herbal medicines advised by local midwives that often lead to reproductive tract infections and finally they undergo sterilization as a means of checking their unplanned and unwanted pregnancies.

It is amply clear that an understanding of the ‘unmet’ need for contraceptive use is critical towards developing a strategy towards increasing contraceptive prevalence. Contraceptive prevalence is a key to improved reproductive health and environmental health, and also to demographic and economic development. The heightened demand for effective family planning services for safeguarding reproductive health of women and her children clearly asks for a multilevel model approach so that available contraceptive technology is disseminated to the ‘user’ in a manner that it is understood and at the same time it is also available to the ‘user’ (see Box 4).

There is a marked increase in sexual activity in the adolescent population.

Box 4

Demand net for contraceptive services should address a wide category of people

Sexually-active unmarried teenagers

Women using less effective contraceptive method

Women using an effective contraceptive but use it incorrectly or are dissatisfied

Women with unwanted pregnancies having no access to safe and affordable abortive services

Women who have related reproductive health problems

Adolescents need access to information about sexual and reproductive health and contraceptive choices. They must be able to make their choice to prevent unwanted pregnancies based on informed knowledge of the health concerns and side effects of such contraceptives. Very often adolescents have wrong perceptions of reproductive health matters and consider that there is little risk of pregnancy following sexual activity, and exhibit at the same time an apparent ambivalence towards contraceptive practices that result in unplanned pregnancy (see Box 5). In general, adolescents have very little, if at all, access to reproductive information and counseling.

High teenage pregnancy rates reflect low levels of contraceptive use due to negative perceptions. A combination of sex education at school and an outreach programme rendering contraceptive service provision having close links involving the clinic, local

schools, youth services, social services and voluntary services in the UK resulted in significant rise in service access by young people (11). The ability of such clinic settings in providing outreach programme for counseling and quality care that have extended hours with no requirement of prior appointment provides for a model contraceptive service in urban setting. The outreach programme offering door-to-door

service that was found highly effective with urban, low-income slum settlers was one in which 'well baby' prizes were distributed based on parents' age at marriage and educational status, mother's age at first birth, immunization status of living children, birth interval, contraceptive use and general criteria of health and hygiene. In this manner health workers were able to reinforce and integrate the maternal child health care (MCH) programme, and it served as a tool to monitor the efficacy of local MCH services (12).

Longitudinal data analysis of 10-year community-based access to contraception in Bangladesh has provided a statistical model to determine the changes in reproductive behaviour and motives of respondents exposed to outreach activities (13). The strategy of doorstep distribution of maternal and child health and family planning services through routine visits by trained workers since its inception in 1978 has been instrumental in increasing the contraceptive prevalence rate (CPR), reducing fertility and attaining a considerably higher immunization coverage in children and women in Bangladesh. Economic appraisal of such labour- and cost-intensive programme has led to an alternative strategy in recommending fixed-site clinics or clinics at cluster spots for provision of health and family planning services complemented with reduced system of outreach workers to inform and target hard-to-reach clients as cost-effective service delivery system (14).

According to recent estimates 46 million women resort to abortion of unplanned or

unwanted pregnancies every year; of this 27 million undergo this traumatic event safely and around 19 million mostly belonging to the developing countries undergo unsafe abortion (15). It is crucial that efforts be made to prevent unintended pregnancy, and to provide contraceptive information and services to women of all ages.

What does contraceptive technology offer today? The introduction of the hormonal contraceptive approach was one of the most important events of the twentieth century for women. Although the availability of oral contraceptives (OCs) provided women with greater control of her reproductive lifestyle, long-term usage of OCs were associated with a few health concerns. In this context, while doctors, health care professionals and women should be kept informed of the latest research findings and their clinical implications, open scientific debates should be encouraged amongst experts and then only the conclusions placed before the public. Scientists have now addressed these issues by developing lower dose formulations and non-oral routes of hormone delivery systems. Increasing range of such options of long-term contraceptive systems delivering hormones via subdermal implants, vaginal ring, intrauterine system, and transdermal patch will afford convenient and effective alternatives to oral contraceptives and also provide greater degree of compliance for the individual user (16). Nestorone (R)/ethinylestradiol (NES/EE) based contraceptive vaginal ring is one such approach towards greater user acceptability since the vaginal route of drug administration has been shown to provide emergency contraception (17) and found to

have positive effect on the psychological aspect of both women and their partners (18). The use of contraceptive microbicides delivered via the vaginal route affords to women discrete protection against sexually transmitted diseases including HIV and at the same time provides to the user, freedom to exercise her reproductive rights in her own space and time domains. In this regard a number of potential options are now available which have shown high acceptability among women and their partners.

A systematic review and meta-analysis of all studies on long-term use of OCs published during 1980 to 2002 revealed that third generation low dose OCs increases the risk of both cardiac and vascular arterial events (19). Androgenic and non-androgenic OCs however provide significant reduction in ovarian cancer risk (20). Combined oral contraceptives alter the genital tract microenvironment with upregulated CCR5 expression in cervical intraepithelial CD4+T lymphocytes influencing users' susceptibility to HIV-1 transmission (21). HIV-1 seropositive women on hormonal contraceptives should thus be counseled for condom use due to their increased risk of cervicitis and cervical *chlamydia* infection (22). Differences in the pharmacodynamics of endogenous hormones have been found in women residing in Bolivia compared to women residing in USA providing thereby a biological basis of variations in women's tolerance of hormonal contraceptives and its compliance (23). Clearly the choice for effective contraception is limited and not sufficient to meet the varied needs of women throughout their reproductive lives. In recognition of

this unmet need for greater range of contraceptive choices the World Health Organization and the Rockefeller Foundation undertook an initiative to develop novel contraceptives as a method that a woman can take on only one occasion in any menstrual cycle on an 'as-needed' basis that would be free of the logistical difficulties and the known side effects associated with existing methods of family planning.

The physiological events associated with vascular functioning, development of new blood vessels (angiogenesis) and increased capillary permeability were identified as the new targets in methods to disrupt peri-ovulatory events and ovulation, uterine receptivity and embryo implantation (24, 25). Studies have identified new sets of angiogenic genes as novel targets for antiangiogenic therapies for contraception (26). The finding that progesterone, but not estrogen is critical for embryo implantation and pregnancy (27) led to the successful use of an antiprogestin, mifepristone either as a low-dose, once a month, post-coital agent or as low-dose emergency contraceptive for fertility regulation (28, 29). Use of mifepristone as a once-a-month contraceptive is an acceptable contraceptive option with minimal side effects though high degree of compliance is necessary along with the use of monitor to detect day of ovulation (30). In a multicentre trial conducted in 10 countries by the World Health Organization, low dose mifepristone (10 mg), levonorgestrel as two tablets (0.75 mg at 12 h interval) or as a single dose (1.5 mg) were very efficacious

for emergency contraception and could prevent pregnancies if taken within 5 days of unprotected intercourse (31). A greater awareness of the safety, efficacy and availability of emergency contraception (EC) is required to prevent unplanned pregnancies and induced abortions in India. Progesterone-regulated genes involved in receptivity and vascular integrity may become the future targets of tailored post-coital contraception to be used by women on 'as needed basis'.

A summary highlights the improved quality care in contraceptive choice (Box 6) and improved method choice (Box 7) in modern contraceptive technology. It is predicted that existing and new scientific information in contraceptive and reproductive health technology may influence strategic policies and global commitments towards improving human health conditions and thereby translate a second contraceptive revolution.

Finally, Box 8 provides a strategic vision of how reproductive health care management may be employed towards the use of modern contraceptive technologies in developing countries like India. The recent launching of the Public Health Foundation in India by the Prime Minister of India permit us to dream a new beginning in reproductive health care management in India that can only be sustained by the 'nine pillars of human dignity': Food, Sanitation, Education, Potable water, Health, Employment, Shelter, Environment and Security (32).

Box 6**Improving access to quality care in family planning^a**

Low Dose Combined Oral Contraceptives (COCs) inhibit ovulation. COCs can be used by women until menopause with no restriction based on parity; can be given immediately post-abortion; may alleviate symptoms of endometriosis and dysmenorrhoea; reduce risk of ovarian cancer. COCs should not be used by women who breastfeed <6 weeks to 6 months postpartum; nonbreast feeding women <21 days postpartum; by smokers; women with multiple risk factors for cardiovascular diseases; hypertension; women with deep venous thrombosis/pulmonary embolism; ischaemic heart disease; stroke; hyperlipidemias; complicated valvular heart disease; migraine; neurologic symptoms; breast cancer; diabetes >20 years; nephropathy/retinopathy/neuropathy associated with diabetes; gallbladder disease; active viral hepatitis; mild and severe cirrhosis; liver tumours; on drugs such as antibiotics, anticonvulsants, carbamazepine, barbiturates which affect liver metabolism.

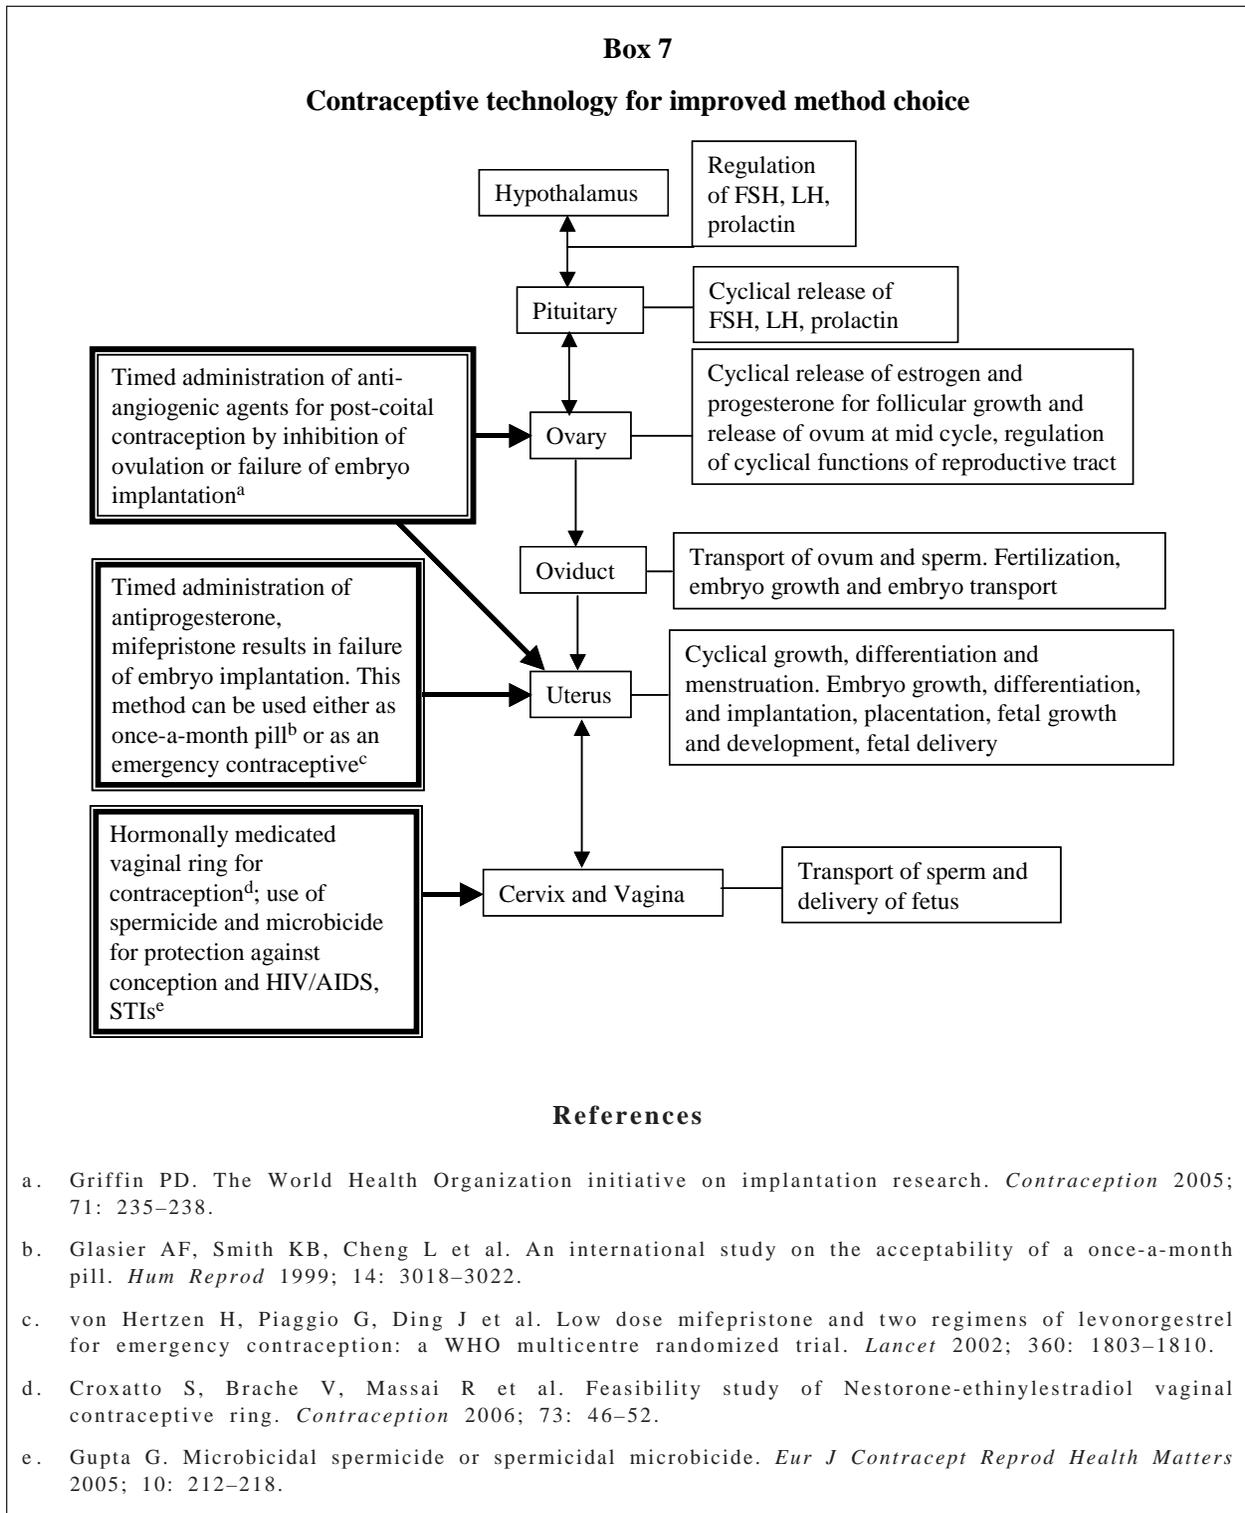

Combined Injectable Contraceptives (CICs) Cyclofem and Mesigyna provide for the release of natural estrogen plus a progesterone. The action of estrogen in CICs may be more physiologic and less potent than the synthetic estrogen present in COCs. The contraindications are the same as for the use of COCs.

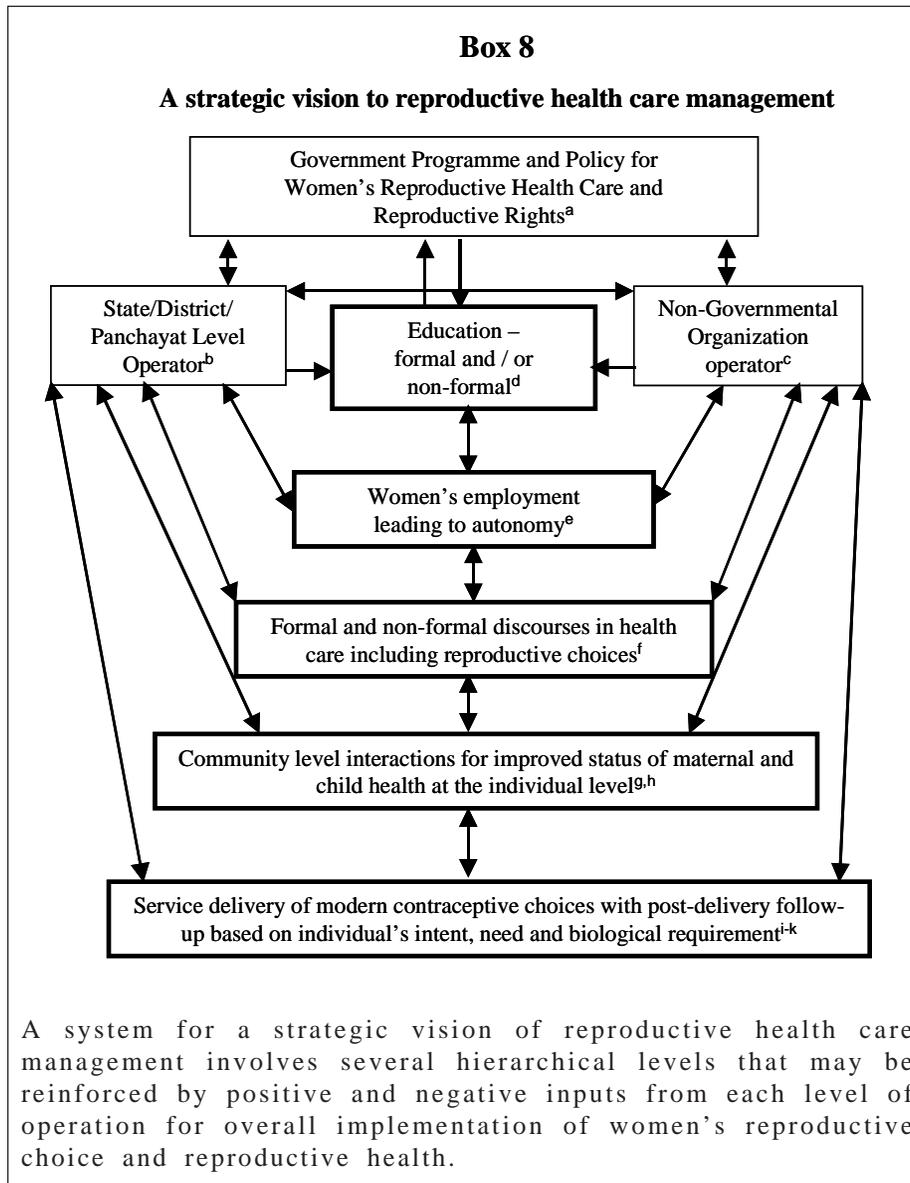

Progesterone Only Contraceptives (POCs) include the Progesterone-only-pill (POP), depomedroxyprogesterone acetate (DMPA)/norethisterone enantate (NET-EN), Norplant and Norplant II implants. POCs do not consistently inhibit ovulation, act on cervical mucus and tubal motility to inhibit sperm transport. POCs also affect endometrium and interfere with embryo

implantation. POCs may be given to non-breastfeeding women immediately postpartum and also to breastfeeding women though neonate may be at risk of exposure to steroid hormone; may be given immediately post-abortion; weight-gain with long-term POCs. POCs should not be used by women <6 weeks post partum; in women having deep venous thrombosis/pulmonary embolism; ischaemic heart disease; stroke; neurologic symptoms; breast cancer; severe cirrhosis; liver tumours. POP and Norplant should not be used by women on drugs such as antibiotics, anticonvulsants, carbamazepine, barbiturates which affect liver metabolism. Women showing unexplained vaginal bleeding should not use DMPA/NET-EN and Norplant. Women having neuropathy/retinopathy/neuropathy and other vascular diseases associated with diabetes should not use DMPA/NET-EN.

Intrauterine devices (IUDs) include copper containing IUDs and levonorgestrel-releasing IUD (20 µg/24 h) alter uterine milieu to prevent embryo implantation in the uterus. IUDs can be inserted immediately after first trimester spontaneous or induced abortion. IUDs should not be inserted during pregnancy because of serious risk to pelvic infection and septic spontaneous abortion. IUDs should not be inserted between 48 h and 4 weeks post partum and to women having puerperal sepsis; in women with anatomical abnormalities of uterus; unexplained vaginal bleeding; cancer of breast, endometrium or ovarian; uterine fibroids causing distortion of uterine cavity; benign or malignant trophoblastic disease; pelvic inflammatory disease; sexually transmitted diseases; HIV/AIDS; and in pelvic tuberculosis.

The need for contraceptive services remains high in India, with over 1 in 3 women (35%) reporting a need for contraceptive advice, as per the MSI study. Providing uninterrupted abortion and contraceptive counselling, devices and care services are essential to safeguard the reproductive rights of women, and protect them from abuse. These services must continue through measures such as telemedicine, incentives to local clinics to open their doors, resolving drug supply chain disruptions, besides improving access to health care. A unique smartphone app developed by an Indian-American researcher from the Johns Hopkins University has helped married rural women in India better understand contraceptive choices, leading to a dramatic increase in women using modern family planning methods in just a few months. According to Sanjanthi Velu, Asia team lead at the Johns Hopkins Centre for Communication Programs (CCP), women who watched motivational videos on the app called "Gyan Jyoti" were 4.5 times more likely to use modern contraceptive methods than those who did not. "This shows that mobile technology provides an innovative and dynamic platform for social and behaviour change communication," Velu said.

JAIPUR: Use of modern methods of contraception among married women in the reproductive age group has increased from 52% in 2016 to 59% in 2020 in the .Â Thirty five percent of women who needed to visit a health facility during Covid-19 restrictions were unable to access health services. Almost 15% of women left their current community to avoid Covid-19, it said. The study is conducted by IIHMR University, Jaipur in collaboration with Jhpiego, Bill & Melinda Gates Institute for Population and Reproductive Health at the Johns Hopkins Bloomberg School of Public Health with support from the department of health & family welfare, Rajasthan. PDF | The spurt in contraceptive technology particularly in spacing methods has opened up a wide variety of contraceptive choice for the potential user | Find, read and cite all the research you need on ResearchGate.Â The current use of spacing methods in India is 7%. People still today are unaware of the importance of use and effectiveness of the spacing methods. Add to this the family planning delivery system is also not completely successful in reaching the methods to the target population and failed to achieve its goal to provide planned family to the nation. Under this situation the Indian population is far away and could not make use of the spurt in the contraceptive technology.
