

The Role of Taiwanese Foreign Direct Investment in China: Economic Integration or Hollowing-Out?

Chen-Min Hsu* · Wan-Chun Liu**

The purpose of this paper is to examine the allocation of the FDI flows in the East Asian region among Southeast Asian countries and China. In addition, it will also investigate the role of the public policy and the private firms during the foreign direct investment process in 1990s. In particular, we will emphasize the Taiwan case, since Taiwan has been one of the main contributors in this region. And we will show the dynamics of the industry types of foreign direct investment during 1990s. It appears that foreign direct investment plays the main role of economic integration between Taiwan and China during the process. However, the expansionary outward FDI may cause a hollowing-out of Taiwan domestic industries.

JEL Classification: C25, F23, L22

Keywords: FDI, economic integration, probit model, hollowing-out

1. INTRODUCTION

The amount of net foreign direct investment in developing countries has climbed more than twelvefold since 1980 according to the IMF data. Long-term foreign investment could provide developing countries with important benefits. Public sector infrastructure projects are in greater demanding.

* An earlier version of this paper was presented at "the Korea and the World Economy, III" Joint Conference of AKES, KDI and RCIE held at the Sungkyunkwan University, Seoul, Korea, July 2004. The authors are grateful for the helpful comments and suggestions from Professors Chan-Hyun Sohn, Yang-Taek Lim, Jung Dong Park, Hyun-Hoon Lee, Chung Mo Koo, Hang Keun Ryu, and two anonymous referees of this Journal.

However, in the private sphere, the long-term foreign direct investment could expand the capital stock in the host country.

The FDI (Foreign Direct Investment) in the East Asian area is quite active since 1990. Taiwan, Korea, Hong Kong, Singapore, as well as Japan are the main contributors of FDI flows in this region, while China and the Southeast Asian countries are the demanders of these flows.

The 1997-1998 Asian Financial Crisis had caused the direction of the FDI flows to change. This is particularly clear in the allocation of foreign direct investment funds between crisis countries in the East Asia and China. For example, the FDI flows from Taiwan to China increased over the last ten years. The proportion of FDI to China comparing with those to the crisis countries increased steadily after 1997.

Although there are several driving forces behind the economic integration in the East Asian region, for example, technology, preference and public policy, it appears that the private enterprises have been playing the main role during the process. The purpose of this paper is to examine the allocation of the FDI flows in the East Asian region among Southeast Asian countries and China. In addition, it will also investigate the role of the public policy and the private firms during the foreign direct investment process in 1990s. In particular, we will emphasize the Taiwan case, since Taiwan has been one of the main contributors in this region. And we will show the dynamics of the industry types of foreign direct investment during 1990s. It appears that foreign direct investment plays the main role of economic integration between Taiwan and China during the process. However, the expansionary outward FDI may cause a hollowing-out of Taiwan domestic industries. The prospect of this trend will be projected in this paper.

The investment risk from the firm's prospect will be explored through the questionnaire to the Taiwan firms doing investment in China. The balance between economic security (or country risk) and individual firm's investment risk will be examined so that policy implications could be drawn from this study.

The remainder of this paper is organised as follows. Section 2 describes

the pattern of Taiwanese FDI. Section 3 describes the data characteristics. Section 4 summarises the empirical results. Section 5 concludes the paper.

2. THE PATTERN OF TAIWANESE FDI

The idea that the pattern of FDI differs depending on the source of investment was suggested by Kojima (1973). He argued that FDI originating in Japan was in line with the host country's comparative advantages and results in a trade promotion effect. In contrast, Kojima (1973) claimed that FDI originating in the U.S. did not conform to the host country's comparative advantages and resulted in a trade reduction effect. The difference came from the fact that Japanese FDI emanated from competitive industries while the U.S. FDI came from oligopolistic industries. That is, the difference in domestic market structure leads to difference in overseas operations, which in turn account for the different effects of FDI.

Kojima's argument challenges orthodox FDI theory based on Hymer (1960), which asserts that FDI only comes from oligopolistic firms possessing some kind of intangible asset. According to Hymer, an intangible asset is prerequisite for FDI because it offsets the disadvantages suffered by a transnational firm when it operates in a foreign country. In contrast, Kojima explained that Japanese firms from competitive industries invested abroad because of changes in macroeconomic conditions in Japan, which made it impossible for firms to continue producing at home. However, Kojima's competitive firms must also possess some industry-specific intangible asset, otherwise, these firms would have chosen to switch to a new industry, one which is favored by the changed macroeconomic conditions at home, instead of venturing abroad to carry on the old business. In this sense, Kojima's firms are not so competitive after all, for any intangible asset generates an economic rent which is non-existent in a competitive industry. And economic rent is what a FDI firm seeks to internalize through transnational operations when the existing markets do not

enable the firm to extract this rent through other arrangements such as licensing or direct export (Buckley and Casson, 1976).

Kojima's idea that his firms are competitive firms may stem from the observation that a substantial proportion of Japanese FDI in manufacturing is undertaken by small and medium-sized firms and on a smaller scale than by American firms.

Likewise, Taiwanese firms started to make substantial direct investment in Southeast Asia in 1980 and in China in 1991 and behaved like Kojima's Japanese firms. That is, Taiwanese FDI is dominated by small and medium-sized firms. The intangible asset possessed by these firms is related to their ability to conduct small scale and flexible production. That small scale firms are able to conduct this is due to their support by an efficient production network encompassing a larger number of highly specialized producers. Firms in the networks are generally independent and are constantly competing among themselves, but they share production and market information that enables them to react quickly and fruitfully to change in technology and market (Perrow, 1992).

In addition, like Japanese FDI firms, Taiwanese firms faced terrible conditions in the domestic investment environment since the late 1980s. Land prices increased sharply and the wage rate was raised up, while the Taiwan dollar appreciated. Firms attempted to escape from the worsening domestic investment environment and turn to foreign investment to keep their export markets and competitiveness in the industries. That is, FDI appears to play a defensive role in retaining export markets for firms under adverse investment conditions at home. Such kinds of defensive FDI is a substitute for domestic production.

However, started from mid 1990s, Taiwanese firms increased their foreign investment to exploit their assets, such as patents, other technological assets, reputation, skills in production, marketing, and advertising. The FDI plays an expansive role in the international market and it is quite complementary to domestic production.

Table 1 Approved Taiwanese Outward Foreign Direct Investment

(unit: US \$ 1,000)

Year	Total (%)	Southeast Asia (%)	China (%)
1994	2,578,973 (100)	397,731 (15.42)	962,209 (37.31)
1995	2,449,591 (100)	326,098 (13.31)	1,092,713 (44.61)
1996	3,394,645 (100)	587,268 (17.30)	1,229,241 (36.21)
1997	4,508,368 (100)	641,241 (14.22)	1,614,542 (35.81)
1998	4,815,511 (100)	477,494 (9.92)	1,519,209 (31.55)
1999	4,521,793 (100)	522,180 (11.55)	1,252,780 (27.71)
2000	7,684,204 (100)	389,446 (5.07)	2,607,142 (33.93)
2001	7,175,801 (100)	523,339 (7.29)	2,784,147 (38.80)
2002	7,228,803 (100)	210,863 (2.92)	3,858,757 (53.38)

Note: Southeast Asia refers to Malaysia, Singapore, Thailand, Indonesia, the Philippines and Vietnam.

Taiwanese FDI is concentrated in less-developed, such as China and Southeast Asian countries. The pattern shifts toward American countries and Europe after 1996 under the “go-slow, be patient” policy, which puts a US\$50 million and US\$60 million cap on any single investment in China as well as the strike of the Asian financial crisis (see Table 1). However, since 2000, Taiwanese FDI toward China surged due to the high economic growth in China and political instability in Taiwan. It is expected that

Taiwanese FDI toward China will continue growing in the next ten years, since go-slow policy has been decided to be abandoned and be replaced with the new “active openness and effective management” policy. According to this new policy, Taiwan entrepreneurs will be allowed to make investment directly in China, except those might cause any damage to Taiwan’s national security. In addition, both Taiwan and China of the two sides across the Taiwan Strait are to become members of the World Trade Organization in November 2001. Trade related investment will be enhanced therefore.

The effect of outward FDI on Taiwan domestic industries is a subject of continuous debate. Using the firm-level data during 1986 to 1994, Chen and Ku (2000) found that FDI will strengthen rather than weaken the viability and competitiveness of domestic industries. However, our study will show that this trend is changing. Domestic production and investment in Taiwan were shrunk over time.

3. DATA CHARACTERISTICS

Whether Taiwanese FDI in China had adversely affected the industry growth in Taiwan has been seriously concerned. A negative association of parent production with production of affiliates would suggest a displacement of labor-intensive production to lower-waged country like China. However, a positive association would suggest either an expanding market share or requiring intermediate goods from the parent company. Theoretically, it is impossible to determine whether the net effect on production is positive or negative.

According to the statistical data from Ministry of Economic Affairs, the induced export from Taiwan to China due to the foreign direct investment in China had been raised to 37.67% of total export in 2000. In effect, if we follow the official statistics from China, the export of FDI inducement is about 56.22% of total export from Taiwan to China. Our research is based on the 2002 survey data which had been published in August 2002.¹⁾

Source: 1998~2003 survey on foreign investment by manufactures (Ministry of Economic Affairs).

It should be noted that the 2003 survey data published in October 2003 is also available. There were cross-sectional survey data conducted by Ministry of Economic Affairs. The 2002 survey data on foreign investment by manufacturers shows that firms investing in China thought that the material and intermediate products imported from Taiwan increased by some 19.60% and 16.56% respectively compared with those in 2000, while the material and intermediate products purchased from the other Taiwanese affiliates in China increased about 34.13% and 26.59% respectively in the year 2000 as compared to the year 2000. The samples are in the list of manufacturers that were permitted to make foreign investment by the Investment Commission of Ministry of Economic Affairs. The 2002 survey sample consisted of 3,481 manufacturers, while there were 3,467 manufacturers in 2003 survey sample.

The 2002 and 2003 sampling data includes 2,170 and 1,852 manufacturers respectively excluding those closes, moved out, and withdrawn from

this data.

investing. Based on these sample, it shows that by the end of 2001 and that of 2002, Taiwan foreign investment in China (including Hong Kong), Southeast Asia and other developed countries (including the U.S.) accounted for 70%, 12.49% and 12.40% of total Taiwanese foreign investment respectively (see Table 2). It's worth to mention that Taiwanese foreign investment in China has increase trend. Table 3A shows that there's no change on expanding parent company's production scale after foreign investment for some 50.89% of the manufacturers in China, while 32.78% think that it has benefit on expanding parent company's production scale. In addition, Table 3A also shows that in 2001 about 35.85% of the manufacturers in all investment areas think benefit on expanding parent company's production scale after foreign investment, while 50.65% firms think that it has no change and detrimental were 50.65%.

Table 4 shows that when the causes of investment are to expand export market, to demand by foreign customers, follow Taiwan consumers, incentives from investing area, cost savings such as land acquirement, material supply, cheap labor, deterioration of domestic investment environment, reduce exchange rate risk, and most-favored nation treatment, the foreign direct investors answer "no change" on expanding their domestic production scale. In contrast, firms making outward foreign investment because of acquirement of land, capital utilization, and overcome trade barrier think benefit on expanding their domestic production scale. Table 5 shows that in 2001 most Taiwanese FDI is horizontal integration, while about 721 firms adopted the forward or backward integration. The firms which horizontal integration and irrelevant product inclined to think not change on expanding the parent company's production, while vertical integration tends to think benefit. Table 6 suggests that large, medium and small FDI firms are inclined to think benefit or not change on expanding parent company's production.

As for the R&D activities of manufacturers with foreign direct investment, Table 7 shows that 79.72% of the firms with FDI in China have R&D department in their domestic institutes in 2001. It suggests that R&D

Table 4 Causes of Investment and Expanding of Domestic Scale

(unit: No. of firms)

Domestic Scale Cause of Investment	Beneficial	No Change	Detrimental	Total

Source: See Table 3A.

Table 8A shows the distribution of investment type of Taiwanese foreign investment. Despite the growth rate of Taiwanese outward foreign direct investment in manufacturing industry has shown a declining trend, it is still the largest outward foreign direct investment industry and accounted for 82.61% of total sample in 2001. Among them, electrical, electronic machinery and repairing industry owns the largest share and accounted for 31.65%, followed by the industry of fabricated metal products with 9.63%. Similar results were found in Taiwanese foreign investment in China as shown in Table 8B of the type of industries by investing area. It is shown that machinery and equipment, computer, communication and video and radio electronic products, electronic parts and components, and electrical machinery, supplies and equipment were also the major investment industries of Taiwanese foreign direct investment in China.

4. EMPIRICAL ANALYSIS

Since the survey data used are measured by discrete or ordered scales. We specified regression models with discrete dependent variables to analyse the variation of production and R&D strategies after foreign investment. Expanding the domestic production scale is categorized as detrimental, no change, and beneficial, which are indicated by an ordered scale 0, 1, 2. We specified an ordered probit model to analyse the effects of FDI. We wish to examine the factors that would result in Taiwanese FDIs which might be mainly complementary or substitute.

The type of investment is divided into four types, i.e. market expansion, technology acquirement, cost savings and others, based on the causes of investment that were described in the questionnaire. Three dummy variables are created to represent four types of investment motivation. Cost savings are classified as defensive investment elements and their expected coefficient signs are thus negative. However, market expansion and technology acquirements are both expansive investing elements and their expected coefficient signs are positive.

The ratio of foreign investment to total investment in 2001 is used as an explanatory variable to the relationship between foreign investment and domestic investment. If FDI has a squeeze impact on domestic investment, then its sign is negative, while if it has a supplementary effect, then the sign is positive.

The sales ratio variable is calculated as the foreign operating revenue relative to total operating revenue. We expected that sales ratio has a positive effect on expanding domestic production.

Parent firms with profit are assigned code 1, otherwise 0. It is expected that the parent firms with profit after investing in foreign countries will keep expanding their domestic production. The coefficients of profit status are expected to be positive. As for firm size, it is divided into three types—small, medium and large firms. Two dummy variables are created to represent three types of firm size. Those firms that have more than 200

employees is defined as large firms and are assigned code 1, otherwise code 0. And if the numbers of firm's employees is less 99, we are defined as small firm. It is expected a large firm tends to expand their domestic production. The coefficient of large firm is suggested to be positive. However, for a small firm, it may be pushed to a less-developing country due to the deterioration of domestic economic environment, and therefore the coefficient of small firm is expected to be negative.

Three variables are created to indicate the characteristics of each firm. One is labor-intensive industry, i.e., those firms which labor input of foreign production is higher and is assigned a code of 1, otherwise 0. Another is electrical & electronics industries. That is, those firms in computer, communication and video and radio electronic products, electronic parts and components and electrical machinery, supplies and equipment are denoted electrical & electronics. The other is fabricated metal products industry. The summary statistics for the explanatory variables is reported in Table 9.

Table 10 reports the ordered probit model results for domestic production scale strategy. Table 10 shows that market expansion and technology acquirement have a significant positive effect, while cost savings has significantly positive effect on domestic production strategy. It also shows that the FDI in China and Southeast Asia have a significant negative effect. Both the vertical integration and horizontal integration are important factors to parent production strategy. After investing in foreign countries, firm size has a little effect on their parent production strategy. It also suggests that ratio of foreign investment has an insignificantly negative effect on the parent scale. Also, firms with profit have a significantly positive effect on their domestic production strategy. Similarly, the estimated coefficient of labor-intensive and electrical & electronics are significantly positive. Likewise, the parent R&D has significantly and positively affected on parent production scale strategy. Our results therefore indicate that Taiwanese FDI, may or may not cause a "hollowing-out" of domestic industries, which depends on the characteristics of each industry. For example, chemical, fiber textile and technology industries which have highly specialization with

Note: ***, ** and * indicate significance at 1,5, and 10% level, respectively. Numbers in parentheses are t-statistic. The estimation software package used is LIMDEP 8.0.

The estimated coefficients should be interpreted in the sense that they

affect the probability that a certain event will occur. This interpretation can be obtained by computing the marginal effects from the estimated model. The marginal effects measures the change in the probability of each choice with respect to a change in an explanatory variable, *ceteris paribus*. Note that the sum of the marginal probabilities of selecting any of the three categories of expanding the domestic production scale equals zero. The results of marginal probabilities are also presented in Table 10. It shows that those factors such as market expansion, technology acquirement and cost savings induce firms to expand domestic production scale. The probabilities were 7.10%, 10.74% and 5.92% respectively. Also, large firms with high probability wanted to expand domestic production scale only with probability 1.09%, while small firms even thought that expansions of scale do harm to them. Those firms in labor-intensive and electrical & electronics industries have high probability to expand their domestic production scale. The probabilities were 9.89% and 11.74% respectively. However, Taiwanese firms in China and Southeast Asia comparing with those in other areas to think that domestic production expansion was detrimental. Those firms with parent R&D, horizontal and vertical integration have higher probability to expand their domestic production scale.

Due to statistically significant effect from the FDI in China and Southeast Asia on parent company production strategy, we further investigate whether there is any different factor on investment in developed countries, China and Southeast Asia by Taiwan's enterprises. The analytical results are shown in Table 11. Table 11 suggests that FDI in China with market expansion oriented has positive effect on domestic production, while there is supplementary effect of cost savings motivation. The significant and positive effects for FDIs in China and Southeast Asia show that there exists production supplementary for Taiwan exports. Both estimated coefficients of horizontal integration and vertical integration are significant. In addition, except FDI in developed countries, firm size coefficients are statistically insignificant for FDIs in China and Southeast Asia. It also shown that ratio of foreign investment coefficients are insignificantly negative. This reflects that FDI has little substitution effect on domestic investment.

shown in Table 12. Table 12 shows that large firms will enhance their R&D activities. And firms that are motivated to expand into foreign markets and rely on technology from domestic parent companies are more inclined to conduct R&D activities. Also both horizontal and vertical integration production have positive effects on conducting R&D activities. In addition, foreign affiliates that rely on parent companies, technology lead their parent companies to conduct more R&D activities. Moreover, the R&D in foreign affiliates is complementary to that in the parent firm.

5. CONCLUDING REMARKS

The paper investigates the variation of production and R&D strategies after foreign investment. We found that market expansion, technology acquirement, cost savings, investment in China and Southeast Asia, type of production, profit status, labor-intensive and electrical and electronics industries, and parent R&D are important factors on parent domestic production strategy after foreign investment. However, the firm size has little effect on expanding domestic production. And FDI has little substitution effect on domestic investment. In addition, we have also found that the driving force of economic integration between Taiwan and China is technology rather than public policy. Taiwanese FDI toward China plays an important role during the economic integration process. Table 13 presents the evolution of Taiwan and China (including Hong Kong) exports and imports of goods and services as a percent of GDP from 1990 to 2000, as well those between Taiwan and Southeast countries. The ratios are steady

and linear over the last decade. And the average growth rate of trade and exports in two regions are about the same rate, i.e., 6.4%.

It should be noted that the trade pattern of Taiwan's trade in the East Asian region indicates that factors other than free trade agreements (e.g., NAFTA and European Union) are important for increasing regional trade. Taiwan is not a member of regional free trade area, yet the share of its trade involving other emerging East Asian countries increased over the last ten years (see Table 13). The Association of Southeast Asian Nations (ASEAN) formed a free trade area in 1992 with an agreement of Common Effective Preferential Tariff (CEPT). Following the creation of the free trade area, the share of regional trade rose from 14% in 1990 to 18% in 1999 (see IMF's *Direction of Trade Statistics*). Since both Taiwan and China became members of the World Trade Organization (WTO) in 2002, it is expected the intraregional trade across the Taiwan Strait will be spurred by an overall reduction in the level of trade barriers.

Recent trade integration across Taiwan Strait has been technology-driven and it will be accelerated by the WTO agreements in the future. It is always pointed out defensive Taiwan FDI, especially those labor-intensive industries, seeks cheap labor in the host countries to reduce the cost of production may cause a "hollowing-out" of domestic industries. And this worry cannot be refuted from a microeconomic perspective by utilizing firm data as shown in this study. However, as the non-labor-intensive industry grows and expansionary FDI is undoubtedly beneficial to domestic industries, we will expect larger FDI in this region, including China and Southeast countries. The economic integration will be more closely, as Taiwan government decided to relax the limits on Taiwan outward FDI in China. In fact, direct investments by domestic producers in such sectors as automobiles, semiconductors and chemicals have international diversification effect as well as vertical and horizontal integration effects. However, it should be mentioned that those who lack substantial investments in human capital and become unskilled workers in textiles and apparel for example would restrict trade and outward FDIs in this region, since the Stolper-Samuelson theorem

applies to a decline in the relative wage of unskilled labor-intensive goods. Economic integration in this region needs more supplementary proposals including labor mobility as well as capital mobility policies such as tax agreement and investment security treaty. In the next stage, policy as well as technology will be the driving forces behind the regional economic integration.

Foreign direct investment (FDI) signifies capital invested in a country that provides manufacturing and service capabilities for both native consumers and world markets. FDI in China in 2019 was \$137 billion. A host of factors influence FDI in China, such as stability, availability of world investment capital, and government regulatory policy.

1. Capital Availability. FDI is mainly dependent on the available investment capital that may be put into circulation. And in the early 2000s, a thriving global economy resulted in large swaths of investable capital across many nations, that proportionat China Foreign Direct Investment (FDI) increased by 93.1 USD bn in Mar 2021, compared with an increase of 86.2 USD bn in the previous quarter. What was China's Foreign Direct Investment in Mar 2021? Last Previous. Accurate Macro & Micro Economic Data You Can Trust. Explore the most complete set of 6.6 million time series covering more than 200 economies, 20 industries and 18 macroeconomic sectors. Learn more about what we do. The growth of foreign direct investment (FDI) in China has been very impressive during the past 16 years. Since 1993 China has become the second largest FDI recipient in the world and the single largest host country among the developing countries. However, in terms of the regional, sectoral, industrial and source country distribution of FDI inflows into China, several issues are worth studying. This paper finds that, first, the regional distribution of FDI inflows into China has been very uneven and mainly concentrated in the East region, which may reinforce the regional disparity between the Assessing the Role of Foreign Direct Investment in China's Economic Development: Macro Indicators and Insights from Sectoral-Regional Analyses. Dic Lo. Three main findings come out from the analyses in the paper. First, it is found that FDI tends to promote the improvement in allocative efficiency, while having a negative impact on productive efficiency. China has been amongst the world's largest recipient countries of foreign direct investment (FDI) since the early 1990s. In 2002, the first year after the country's accession to the World Trade Organisation, it for the first time surpassed the USA to become the world's largest FDI-recipient with the actual amount of FDI accounting for around 10% of the world total.

Chinese Outward Foreign Direct Investment: Is ASEAN A New Destination? The paper re-investigates the determinants of China's outward foreign direct investment (OFDI) employing panel data analysis collecting between 2003 and 2014. They showed that Chinese development level measured by GDP per capita and investments in human capital had a positive influence on China's OFDI. Their empirical results indicated the important role of firm-industry factors (the degree of competition, foreign presence, and technological development within an industry) and institution-specific factors (favourable government regulatory policy and the level of state ownership in the firm) in explaining China's OFDI. Socialism with Chinese characteristics is the choice China makes in light of its own conditions. After decades of practice and improvements, it has developed unique advantages in coordinating the roles of government and market. The socialist system and institutions prove especially effective in pooling labour, material, and financial resources for massive projects in national and regional development. Foreign direct investment in China peaked in the late 1990s, securing the country's position as the factory of the world. The second stage was from China's accession to the WTO in 2001 to 2012. Increasing integration with the world economy in this decade turned out to boost rather than impair the international competitiveness of Chinese manufacturing. Most developing countries strive to attract foreign direct investment for its acknowledgement as a tool in economic growth and development in developing countries (Eduardo et al. 1998). Moreover, a large and growing body of literature has showed that FDI plays major role to economic development of a country. Therefore, this thesis is going to analyse the relationship between Foreign Direct Investment and economic growth in China. Nowadays, China is one of the most powerful countries and has a crucial role in the political and economical situation of the entire world. It is very important to mention what was the China's situation before 1978. China was isolated in Communist regime, following an autarkic policy. China Foreign Direct Investment (FDI) increased by 97.6 USD bn in Mar 2021, compared with an increase of 86.2 USD bn in the previous quarter. What was China's Foreign Direct Investment in Mar 2021? Last. Previous. Accurate Macro & Micro Economic Data You Can Trust. Explore the most complete set of 6.6 million time series covering more than 200 economies, 20 industries and 18 macroeconomic sectors. Learn more about what we do. Foreign direct investment (FDI) signifies capital invested in a country that provides manufacturing and service capabilities for both native consumers and world markets. FDI in China in 2019 was \$137 billion. A host of factors influence FDI in China, such as stability, availability of world investment capital, and government regulatory policy. 1. Capital Availability. FDI is mainly dependent on the available investment capital that may be put into circulation. And in the early 2000s, a thriving global economy resulted in large swaths of investable capital across many nations, that proportionately overwhelmed the number of viable local investment ideas in a given country.
